Synthetic portfolio data: the distributor, its suppliers, its purchase orders and every invoice are invented. Arrival timestamps were spread artificially over 30 days so the daily chart has more than one point; they are not observed arrival times and they move whenever the corpus is reloaded. Review rate and straight-through rate both divide by eligible invoices, which excludes duplicates and unsupported documents.

Submissions received	Unique invoices	Needs review	Review rate	Straight-through rate
200	186	90	0.51	0.49

Submissions and Needs review

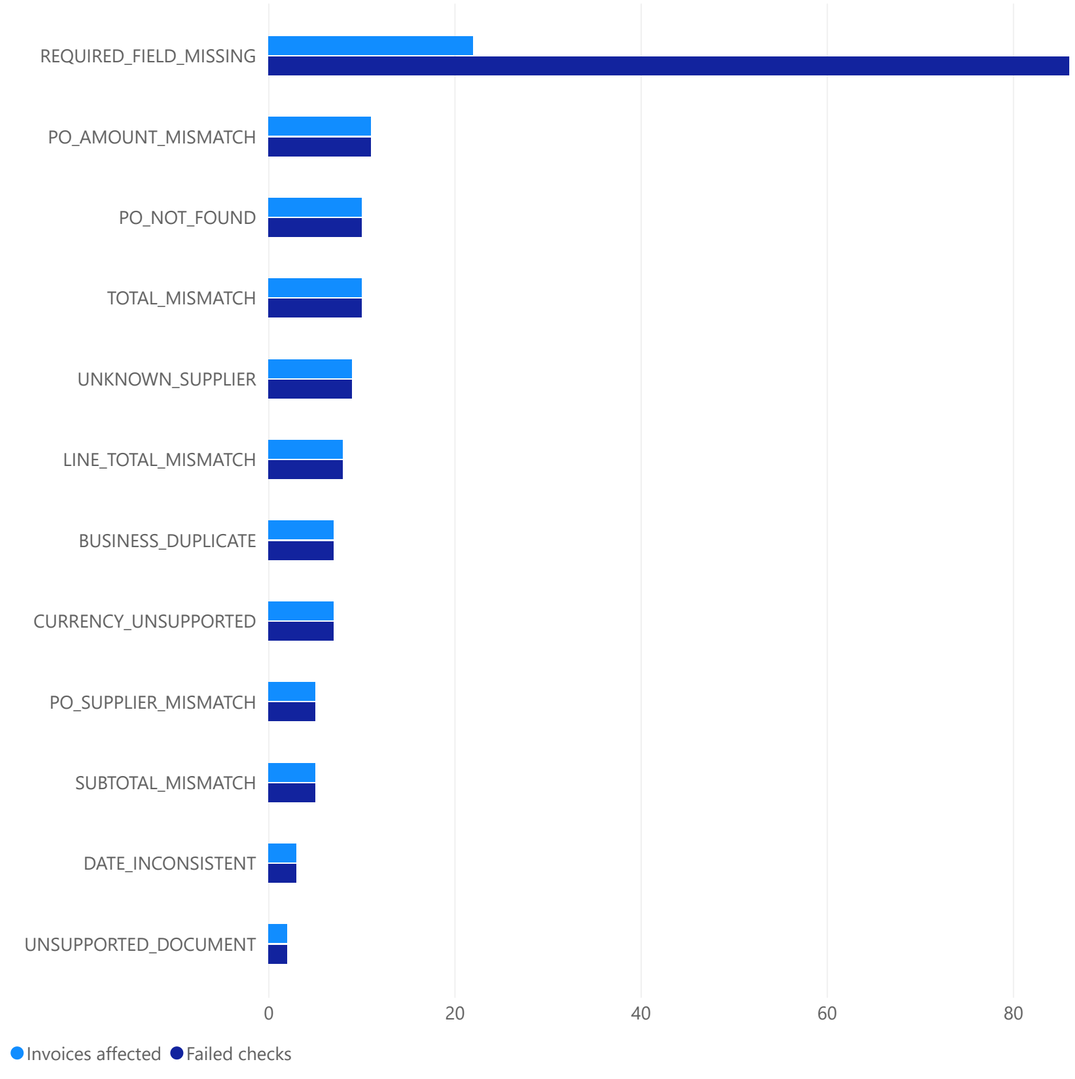

by Arrival date

Synthetic portfolio data. Failed checks on each invoice's current revision only; a problem a reviewer has since corrected leaves this view and remains in validation_results. Invoices affected counts distinct invoices with at least one failure of that code. Failed checks counts individual failures, so one invoice missing four required fields is four failed checks. The two are never summed.

Invoices affected and Failed checks

by Rule code

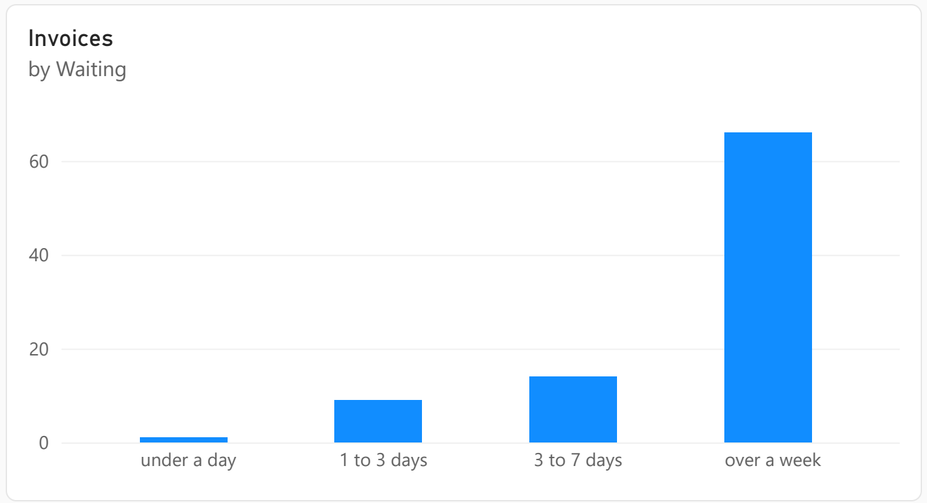

Field	Expected value	Observed value	Supplier

Synthetic portfolio data. One row per canonical invoice, showing its current revision: 186 invoices from 200 arrivals, because a repeat arrival is linked to the invoice it duplicates rather than creating a new one. Waiting time is measured from the artificial arrival timestamps described on the processing overview page and does not represent time any person actually waited. Amounts are recorded invoice values in TND; this project executes no payments. Rows reading "(absent)" are documents whose invoice number could not be read. Each is still a separate invoice, keyed to its own submission rather than merged with every other unidentified document (ADR-005); Invoice id is shown because without it the table collapses them into one row.
